Q. What is the most concentration-sensitive promoter architecture?

sharp response?
cooperative?
proofreading?

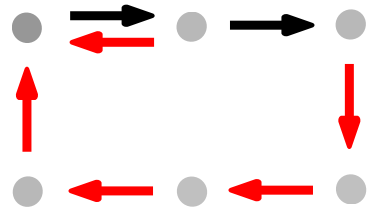

A. It depends on the limiting constraint

1. Cooperativity only optimal above critical concentration

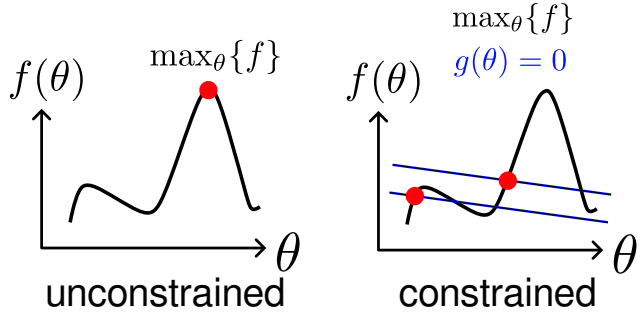

"Keep binding sites free" (diffusion-limited)

"Bind cooperatively" (activation-limited)

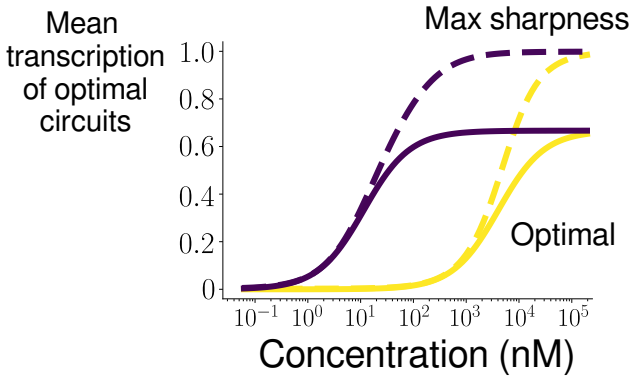

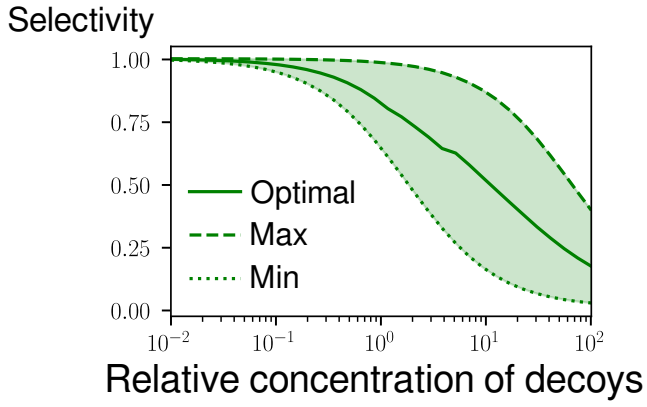

Proofreading only optimal above critical **decoy** concentration

2. Solutions sets are generically **discontinuous**

3. Optimal promoters neither maximize sharpness nor selectivity

Discussing optimality requires precise accounting of underlying constraints
